Descripción general

Objetivos

La aplicación de gestión de ventas tiene como objetivo principal mostrar un listado de productos vendidos en un rango de fechas específico, agrupados por la cantidad total de ventas. Utilizaremos PHP como lenguaje de programación para el desarrollo de la aplicación, junto con una base de datos PostgreSQL para almacenar la información de las ventas. La aplicación se ejecutará en el entorno de desarrollo XAMPP, que incluye Apache como servidor web y PHP como intérprete de scripts, permitiéndonos crear y gestionar la aplicación de manera local.

Herramientas usadas

- XAMPP: Entorno de desarrollo que incluye Apache, MySQL, PHP y Perl.
- PostgreSQL: Sistema de gestión de bases de datos relacional utilizado para almacenar la información de las ventas.
- PHP: Lenguaje de programación utilizado para el desarrollo del backend de la aplicación.
- HTML y CSS: Utilizados para el desarrollo del frontend y la interfaz de usuario de la aplicación.
- VS Code: Editor de código fuente utilizado para escribir, editar y depurar archivos de PHP, HTML, y CSS.
- pgAdmin y DbVisualizer: Herramientas utilizadas para administrar y visualizar la base de datos PostgreSQL.

Estructura

La estructura del fichero está compuesta por una imagen jpg para el banner de la aplicación y un archivo php ventas.php que actúa como una combinación de lógica de backend (PHP), presentación de frontend (HTML) y estilos (CSS). Este archivo incluye:

- Encabezado PHP: Inicia con la lógica de backend, como la conexión a la base de datos y el procesamiento de formularios.
- Sección de Formulario HTML: Presenta un formulario para ingresar un rango de fechas.
- Estilos CSS: Define reglas de estilo CSS para la apariencia de los elementos HTML en la página.
- Tabla de Resultados HTML: Estructura la tabla donde se mostrarán los resultados de la consulta SQL.
- Lógica de Presentación PHP: Maneja la presentación de los datos consultados, incluyendo la iteración a través de los resultados y la generación de las filas de la tabla HTML.

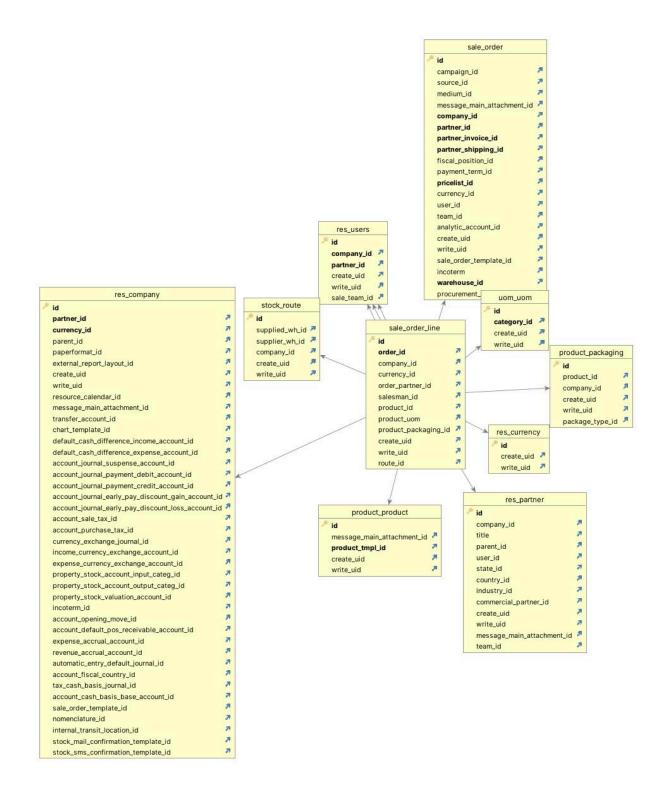

Diagramas y scripts de tablas

En esta aplicación se usan las siguientes tablas de odoo:

sale order line

Esta tabla almacena las líneas de pedido de venta, que incluyen información sobre los productos vendidos, la cantidad, el precio, etc.

Captura DbVisualizer

Script de creación

CREATE TABLE sale_order_line (id SERIAL NOT NULL, order_id INTEGER NOT NULL, name TEXT NOT NULL, sequence INTEGER, invoice_status CHARACTER VARYING, price_unit NUMERIC NOT NULL, price_subtotal NUMERIC, price_tax DOUBLE PRECISION, price_total NUMERIC, price_reduce NUMERIC, price_reduce_taxinc NUMERIC, price_reduce_taxexcl NUMERIC, discount NUMERIC, product_id INTEGER, product_uom_qty NUMERIC NOT NULL, product_uom INTEGER, qty_delivered_method CHARACTER VARYING, qty_delivered NUMERIC, qty_delivered_manual NUMERIC,

Mapa de navegabilidad

1.-Inicio de la aplicación

Nada más iniciar la aplicación, encontramos la imagen en el header, junto con un formulario en el que introducimos las fechas de inicio y de fin para la búsqueda.

Justo debajo se encuentran los 2 títulos de la tabla en la que vamos a mostrar el nombre del producto y la cantidad vendida.

En el footer tenemos la fecha de generación de la consulta.

2.-Introducción de los datos de búsqueda

Introducimos el día, mes y año de la fecha inicio y fin

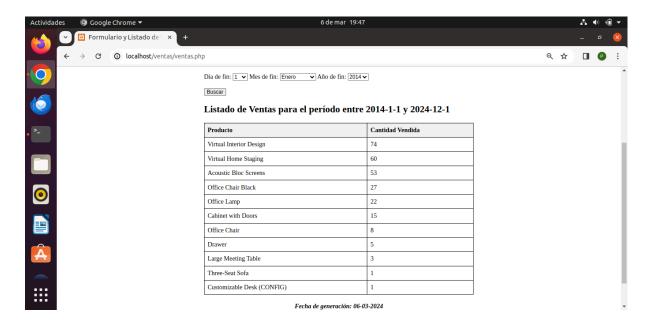

3.-Resultados de la búsqueda

CASO EN EL QUE NO SE ENCUENTRAN DATOS

Si no se encuentran productos en el rango de fechas,simplemente se muestra un mensaje en la tabla

CASO EN EL QUE SÍ SE ENCUENTRAN DATOS

Si se encuentran productos en el rango de fechas, se muestra una lista de los productos encontrados con la cantidad vendida ordenados decrecientemente en función de este último atributo.

Algoritmos principales

Conexión BBDD

En el archivo php.ini,es necesario que la extensión pdo_pgsql esté habilitada. Esta extensión proporciona soporte para PostgreSQL en PHP. Para habilitarla, hay que buscar la línea correspondiente a pdo pgsql en el archivo php.ini y descomentarla.

La primera línea if (\$_SERVER["REQUEST_METHOD"] == "POST") verifica si los datos del formulario se han enviado utilizando el método POST.

Después ,se definen las variables de conexión para la base de datos PostgreSQL de Odoo, como el host, el puerto, el nombre de la base de datos, el usuario y la contraseña. Luego, se utiliza pg_connect para establecer la conexión con la base de datos.

Operaciones CRUD

La aplicación proporciona funcionalidades para buscar y visualizar las ventas de productos dentro de un rango de fechas específico, pero no incluye operaciones directas de actualización o eliminación de datos.

Crear (Create):

El usuario puede ingresar un rango de fechas para buscar las ventas de productos durante ese período.

Este rango de fechas se ingresa a través de un formulario HTML con campos para el día, mes y año de inicio y fin del período de consulta.

Al hacer clic en el botón "Buscar", se envía el formulario y se ejecuta la operación de consulta en la base de datos.

Leer (Read):

Después de enviar el formulario, se realiza una consulta SQL en la base de datos para recuperar las ventas de productos dentro del rango de fechas especificado.

Se muestra un listado de las ventas encontradas en una tabla HTML en la página, que incluye el nombre del producto y la cantidad vendida.

Si no se encuentran ventas en el rango de fechas especificado, se muestra un mensaje indicando que no se encontraron resultados.

Lógica de interés

Obtención de datos del formulario: Se obtienen los valores de las fechas de inicio y fin del formulario enviado por el usuario.

Construcción de las fechas de inicio y fin: Se concatena los valores obtenidos del formulario para crear las fechas de inicio y fin en el formato adecuado para la consulta SQL.

Consulta SQL: Se construye una consulta SQL para obtener los productos vendidos en un rango de fechas especificado. La consulta utiliza varias tablas de la base de datos de Odoo (sale_order_line, product_product, product_template y sale_order) y realiza una operación de JOIN para obtener la información necesaria.

Ejecución de la consulta y procesamiento de resultados: Se utiliza pg_query para ejecutar la consulta SQL en la base de datos y se obtiene un objeto \$result que contiene los resultados de la consulta. Luego, se recorren los resultados utilizando un bucle while y se imprimen en una tabla HTML.

Mostrar resultados en HTML: Se imprime el encabezado de una tabla HTML y se recorren los resultados obtenidos de la consulta para imprimir cada fila de la tabla con los productos vendidos y la cantidad vendida.

Mostrar la fecha de generación: Se muestra la fecha actual utilizando la función date y se imprime en el formato deseado.

Cierre de la conexión a la base de datos: Finalmente, se cierra la conexión a la base de datos utilizando pg close.
